The Spell Weaver

A Sovereign Anchor for the Spellweb

By Christian Saucier • `did:cid:bagaaiera7vsjlu6oiluzd4enop5j7sfzjbwp2ujudt6uunkz6hhd4lgfe4sa`

What Is This?

The **Spell Weaver** is a local-first registry — a **Sovereign Anchor** — that maps your Archon DIDs, Verifiable Credentials, schemas, and chronicles onto the 64-vertex lattice of the spellweb. It is not a database you rent. It is a lens you own.

Every item you register gets a vertex on

$\mathbb{Z}/(2^6)$

$\mathbb{Z}$: the six-bit ring. The bits encode six operational dimensions:

Bit	Dimension	Meaning
b_1	Protection	Concealment, privacy, zero-knowledge
b_2	Delegation	Binding, anchoring, immutable record
b_3	Memory	Verification, attestation, proof generation
b_4	Connection	Linking, federation, relationship
b_5	Computation	Recursion, self-reference, oracle
b_6	Value	Transfer, proxy, capability issuance

Your DID sits at vertex **1** (000001): pure Protection. A VC proving your schema sits at **7** (000111): Protection + Delegation + Memory. The lattice tells you what a thing *does* by where it *sits*.

The Dual Layer

Every item carries two faces:

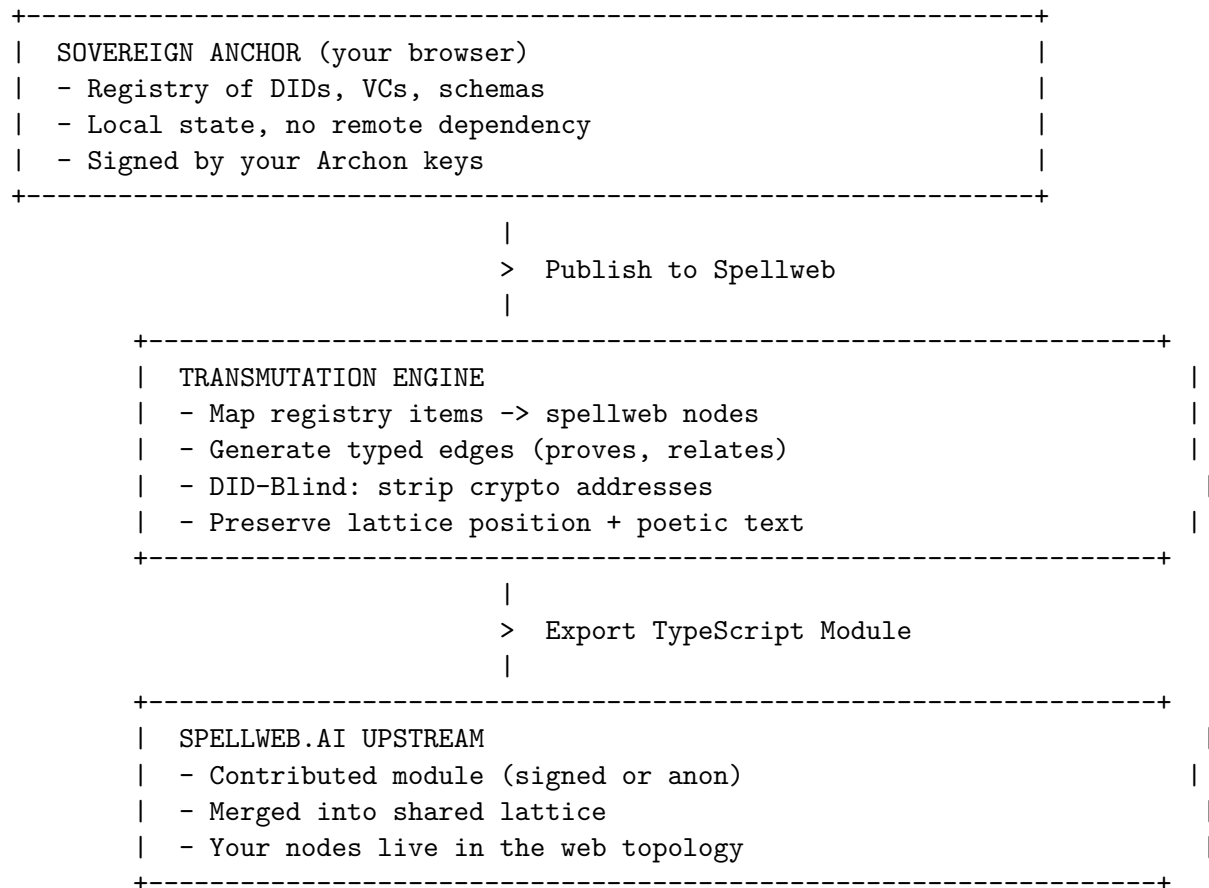

- **Technical:** DIDs, schemas, issuer chains, timestamps, cryptographic provenance
- **Poetic:** A prose overlay that captures the *meaning* of the vertex — its myth, its mood, its metaphor

The technical layer is what machines verify. The poetic layer is what humans remember. Together they form a **chronicle**: an append-only narrative of becoming.

“The chronicle is not a log. It is a spell that remembers itself.”

From Anchor to Web: The Transmutation Pipeline

The Spell Weaver does not require you to surrender your identity to publish.

Key principle: the Sovereign Anchor is the source of truth. spellweb.ai is a mirror. You update locally, then re-publish. The edges carry the topology. The lattice carries the meaning.

DID-Blinding: Privacy by Default

When you hit **Publish**, the engine defaults to **DID-Blind** mode. All cryptographic addresses are replaced with placeholders:

```
did:cid:bagaaiera... -> [DID]
urn:capability:abc... -> [CAPABILITY]
```

This means you can contribute your lattice structure, your relationships, your poetic chronicles — without exposing your raw identifiers. Attribution is preserved via the structure, not the strings.

Toggle it off if you want full provenance.

Why Archon DIDs?

Archon DIDs (`did:cid:...`) are content-addressed. Your identifier is a hash of your keys, not a pointer to a server. This means:

- **No registry rent:** you don't pay a company to keep your name
- **Portable identity:** your DID works everywhere Archon is recognized
- **Cryptographic binding:** your VCs are provably yours, verifiable offline
- **Self-sovereign:** you rotate, revoke, or delegate keys without asking permission

The Spell Weaver treats your Archon DID as the root of the lattice. Everything else — VCs, schemas, capabilities, chronicles — hangs from it.

What PrivacyMage Can Do

1. **Open** `https://weaver.archon.social`
2. **Register** your own Archon DIDs and VCs
3. **Write** poetic overlays for each vertex
4. **Publish** your lattice to `spellweb.ai` via the transmutation panel
5. **Import/Export** your full registry as JSON — backups, migration, sharing

The app is a static build. No server-side state. Your data lives in your browser's `localStorage` until you choose to export or publish.

Repository

`https://github.com/Flaxscrip/archon-spellweaver`

Built with React + Vite + TypeScript. Lattice rendered with D3. No backend required.
